# Cerium

## General Information

## **Discovery**

Cerium was discovered by J.J. Berzelius and W. Hisinger in 1803 in Vestmanland, Sweden. It was first isolated by Hillebrand and Norton in 1875, in Washington, USA.

### **Appearance**

Cerium is an iron-grey, lustrous, malleable metal. It oxidises easily at room temperature.

#### Source

Cerium is the most abundant of the lanthanides and is found in a number of minerals, chiefly bastnaesite (found in Southern California) and monazite (found in India and Brazil). Metallic cerium can be prepared by two methods. The first is the metallothermic reduction of cerium (III) fluoride with calcium, used to produce high-purity cerium. The second is the electrolysis of molten cerium (III) chloride.

#### **Uses**

Cerium is the major component of misch-metal alloy (just under 50%), which is used extensively in the manufacture of pyrophoric alloys for products such as cigarette lighters. Cerium (III) oxide is used as a catalyst in self-cleaning ovens, incorporated into oven walls to prevent the build-up of cooking residues. It is also a promising new petroleum-cracking catalyst.

## **Biological Role**

Cerium has no known biological role.

#### **General Information**

Cerium tarnishes in air and reacts rapidly with water, especially when hot. It burns when heated. It is attacked by alkali solutions and all acids. The pure metal is likely to ignite when scratched with a knife.

Cerium is interesting because of its variable electronic structure. The energy of the inner 4f level is nearly the same as that of the 6s level, and this gives rise to variable occupancy of these two levels and subsequent variable oxidation states.

# **Physical Information**

Atomic Number 58

Relative Atomic Mass (<sup>12</sup>C=12.000) 140.12

Melting Point/K 1072

Boiling Point/K 3699

Density/kg m<sup>-3</sup> 6773 (298K)

Ground State Electron Configuration [Xe]4f<sup>1</sup>5d<sup>1</sup>6s<sup>2</sup>

Electron Affinity (M-M<sup>-</sup>)/kJ mol<sup>-1</sup> 50
